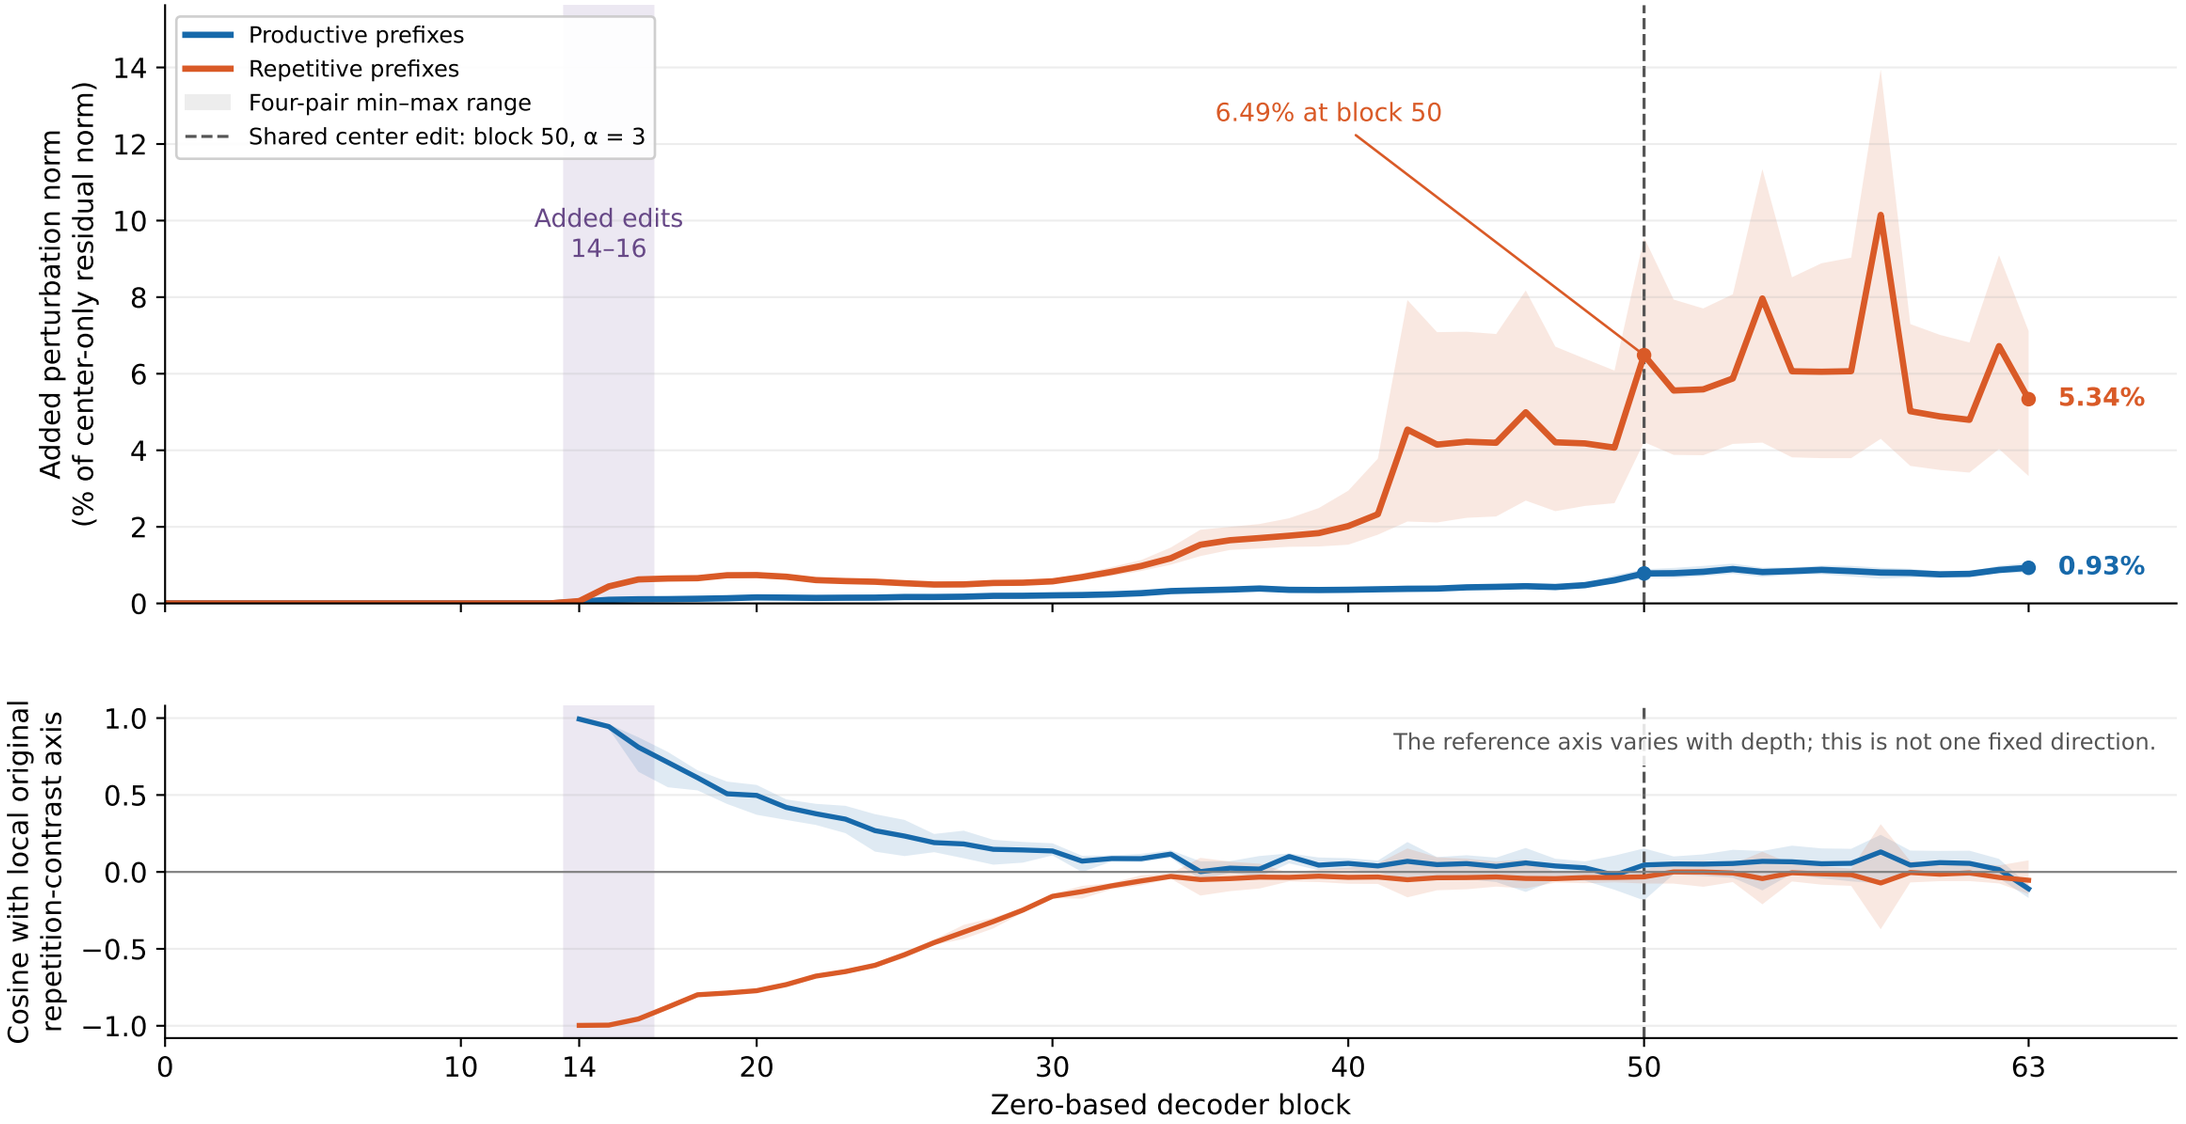
Small early edits produce larger downstream transport on repetitive prefixes

Added α: block 14 = 0.25, block 15 = 1.0, block 16 = 0.25. Both conditions retain identical block-50 weights at α = 3.



Δh = h(early + center) − h(center only). Last-32-token mean residual captures; four constructed prefix pairs.

Lines are means; bands show the four-pair range. Alignment is undefined before block 14, where Δh is exactly zero.

Transport size is not correctness: the separate game answer remained wrong and phylogeny output was unfinished.
